Abstract

Cladocolea spathiflora, a new species from Guerrero, Mexico, is described and illustrated. The new taxon is compared with C. pringlei and C. grahamii, species with similar characteristics; however, the flowers of C. spathiflora are associated to a spathaceous receptacle, while in the other two species the flowers are sessile on the axis of the inflorescence. An identification key and a distribution map of these taxa are included.

Cladocolea spathiflora Galván-Gonz., Cerros, Espejo & López-Ferr., spec. nov. Fig. 1, Fig. 3 A, D, G, J, M

Cladocolea spathiflora is similar to C. grahamii (Bentham) van Tieghem and C. pringlei Kuijt from which it differs by its flowers associated to a spathaceous receptacle formed by the fusion of pedicel and floral bract.

Type:—MEXICO, Guerrero: municipio de Eduardo Neri: 3.1 km al SW de El Miraval, carretera federal Miraval a Filo de Caballos, 2,159 m.a.s.l., 17°42'31.2"N, 99°46'32.7"W, 20 April 2017. L. G. Galván G., R. Cerros T. & M. I. Miguel V. 254 ♂ (holotype: HUMO!, isotype: UAMIZ!).

Introduction

The genus Cladocolea van Tieghem comprises ca. 25 species (Kuijt & Hansen 2015) that are distributed from Mexico to South America. In Mexico, Cladocolea is represented by ca. 20 species (Villaseñor 2016, Martínez-Ambriz & Cruz-Durán 2015, Martínez-Ambriz & Lozada-Pérez 2016) distributed in 17 states, mainly located in provinces of the Trans-Mexican Volcanic Belt, Balsas Basin, Sierra Madre del Sur and Mexican Pacific coast, while in the Mexican Gulf and Chiapas provinces only one species is reported. Recently, Martínez-Ambriz (2014), Martínez-Ambriz & Cruz-Duran (2015) and Galván-González (2016) have reported between 14 and 16 taxa for the state of Guerrero.

During the revision of herbarium collections as a part of the project “El género Cladocolea Tiegh. (Loranthaceae) en México” (Galván-González 2016), we found some specimens that did not match with any of the species so far described. The specimens have alternate to pseudoverticillate leaves, simple and indeterminate to determinate inflorescences and ebracteolate flowers, as a consequence of which we considered it appropriate to place them in Cladocolea. The taxon here proposed is compared with Cladocolea grahamii (Bentham) van Tieghem (1895: 167) and C. pringlei Kuijt (1975: 322), species which may be confused by their similar leaves and because in C. spathiflora the flowers appear to be sessile on the axis of the inflorescence. Additionally, a dichotomous key to determine the species of Cladocolea present in the state of Guerrero is included.
Scandent shrubs with pendant shoots, to 2 m long, dioecious. Stems angulate to quadrangulate, becoming cylindrical when mature, glabrous, caulinar roots on mature stems. Leaves alternate to opposite, regularly three pseudoverticillate leaves, petiole 1.4–5.7 mm long; blades ovate to lanceolate, rarely elliptic, 2.8–7.3 × 1.1–2.9 cm, base cuneate to attenuate, margin corky, apex acute, obtuse or rounded, glabrous, venation of three middle veins with lateral branching, resembling pinnate venation. Inflorescences racemose, indeterminate, rarely determinate, present only in mature branches, 1(–2) by foliar axil; male inflorescences 0.7–3.2 cm long, with 13–21 flowers, peduncle 0.4–2.7 mm long; female inflorescences 0.7–1.8 cm long, with 9–20 flowers; peduncle 0.2–1.9 mm long; pedicel and floral bract fused and forming a spatheaceous receptacle, 2.2–6.3 × 1.9–3.6 mm, associated to the flowers. Male flowers hexameroous, rarely octameroous, floral buds clavate, apex rounded, mature flowers 6.7–8.5 × 3.8–6.5 mm; calyx 2–4 lobed to irregularly dentate, 1.1–1.5 mm long; petals 5.7–7.5 × 0.9–1.5 mm, unicellular trichomes on the adaxial surface, stamens disposed in two unequal series, the short ones 4.0–6.1 mm, the long ones 5.1–7.2 mm, filaments adnate to petals, free in the apical portion, surface bullate, anthers 1.7–2.4 × 0.7–1.3 mm, projection of the connective acute to rounded; vestigial ovary 0.8–1.3 × 1.5–2.1 mm, style 4.9–6.1 mm long, tortuous at central and apical portions; female flowers hexameroous, floral buds cylindrical, apex rounded, mature flowers 6.7–7.9 × 4.2–5.7 mm, calyx 2–4 lobed to irregularly dentate, 1.3–1.9 mm long; petals 5.9–7.5 × 0.9–1.2 mm, unicellular trichomes on the adaxial surface; staminodes with sterile anthers, disposed in two unequal series, the short ones 4.3–5.5 mm long, the long ones 5.3–6.8 mm long, filaments entirely adnate to petals, surface bullate; anthers 0.9–1.4 × 0.6–0.8 mm, projection of the connective obtuse to rounded, ovary 0.8–1.5 × 1.5–2.3 mm, style 5.5–6.9 mm long, undulate to tortuous in the superior half, with 2–4 vertical or horizontal folds. Inflorescence 1.1–2.1 cm long, receptacle concrescent, 2.4–3.3 × 3.5–4.7 mm. Fruits ellipsoid, 1.6–2.7 × 0.5–0.7 mm.

**Distribution and habitat:**—*Cladocolea spathiflora* is known from two regions of the municipality of Coyuca de Catalán and between the municipal boundaries of Eduardo Neri and Leonardo Bravo, in the state of Guerrero (Fig. 2). It is a parasitic plant of oak trees in pine-oak forests, between 1,860 and 2,170 m.a.s.l. It flowers from February to June, the fruits have been reported from March to April. Pollination is carried out by bees.

**Simbolology**

- State of Guerrero
- *Cladocolea spathiflora*
- *Cladocolea grahamii*
- *Cladocolea pringlei*

**FIGURE 2.** Distribution map of *Cladocolea spathiflora*, *C. grahamii*, and *C. pringlei* in Mexico.
Ethimology:—The specific epithet refers to the spathaceous resemblance of the receptacle, formed by the fusion of the pedicel and the floral bract.

Comments:—Herbarium specimens of Cladocolea spathiflora may be confused with dried material of C. grahamii (Benth.) Tiegh. or C. pringlei Kuijt, particularly when the inflorescences are immature. However, the new taxon differs of both species in having regularly three pseudoverticillate leaves, a spathaceous receptacle that support each flower instead of sessile flowers on the axis inflorescences, a tuft of hairs in the adaxial surfaces of the petals in female flowers and staminodes with sterile anthers. Additional differences among these taxa are shown in Table 1 and Figure 3.
